

PV239 – Bonus 1 - Working with Bluetooth

Goals

- Introduction to Bluetooth
- Simple Bluetooth communication demo in .NET MAUI using Plugin.BLE library
- Quick look at implementing resilient Bluetooth request-response communication

Introduction to Bluetooth

- Wireless communication technology for short-range communication
- Operates in the 2.4 GHz ISM band with ranges up to 100 meters
- Commonly used for connecting peripherals (headphones, keyboards, etc.) and IoT devices

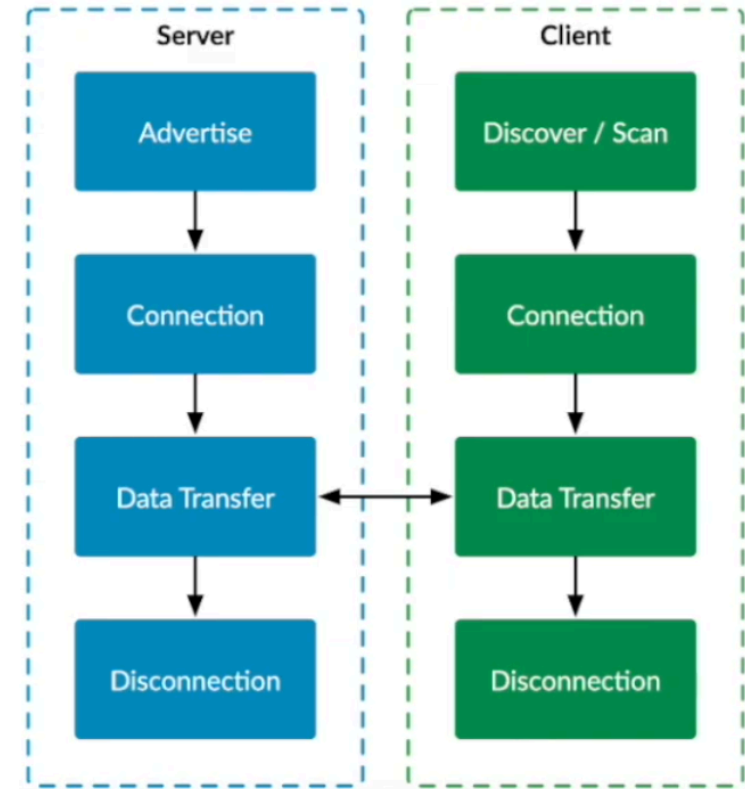

Client-server communication

- Bluetooth uses the client/server model
- Server advertises services and characteristics
- Client is in control of initiating communication and requesting data from the server
- Server responds back to client requests

Bluetooth Connection Steps

1. **Advertising and scanning:** Server advertises, client scans
2. **Connecting:** Client initiates connection
3. **Discovering services:** Client discovers services and characteristics
4. **Reading/writing:** Client reads/writes characteristic data
5. **Subscribing to notifications:** Client subscribes to characteristic changes
6. **Disconnecting:** Either side disconnects when done

Working with Bluetooth in .NET MAUI

- Library [Plugin.BLE[(<https://github.com/dotnet-bluetooth-le/dotnet-bluetooth-le>)]
- Cross-platform support for Bluetooth LE communication
- Provides API for scanning, connecting, discovering services/characteristics, reading/writing data, and subscribing to notifications
